# Aflatoxin Elaboration In *Brassica Campestris* Under Storage

## T. Prasad & S.S. Sahay

Post-Graduate Department of Botany Bhagalpur University, Bhagalpur-812007

(Accepted December, 1985)

From seed samples of *Brassica campestris* obtained from different godowns, 20 fungi and 140 isolates of *Aspergillus flavus* were isolated. Thirty six isolates of *A. flavus* were toxigenic producing aflatoxins  $B_{1}$ ,  $B_{2}$ ,  $G_{1}$  &  $G_{2}$ . Concentration of  $B_{1}$  was high.

*Brassica campestris* (sarson) is an important oil seed crop grown in northern, central and eastern parts of India. Part of the crop is stored. The seeds are kept in bags and stacked and also stored in earthen structures known as "Kothi".

Qualitative analysis of aflatoxin was done on TLC plates using toluene: isoamyl alcohol: methanol (90:30:2 v/v) solvent system (Reddy *et al.*, 1970) and quantitative estimation of aflatoxin B<sub>1</sub> was done spectrophotometrically (Nabney & Nesbitt, 1965). Identity of the aflatoxin was confirmed chemically by tri-fluoroacetic acid (Stack & Pohland, 1975).

During storage, the seeds are exposed to fluctuations in temperature and humidity. Heat produced by the seeds during storage leads to mustiness and association/infection of several fungi. Christensen (1957) reported the manifestation of moulds on seed lots during storage. Some of these fungi are mycotoxic and produce toxin in the seeds. So far no information is available on aflatoxin production in mustard seeds. This problem has been investigated and the cosults are reported.

MATERIALS & METHODS - Isolation of mycoflora was done by the standard blotter and agar tests (ISTA, 1966). Percentage incidence of the fungi was determined on the basis of occurrence of a particular fungal species in 100 samples.

Aflatoxin producing potential of *A. flavus* isolates was tested in liquid rice flour medium Misra & Sinha, 1979). Mustard seed samples were examined under UV light for BGYF test Fennell *et al.*, 1973) and only positive samples **RESULTS** - During winter season, 11 fungal species were recorded of which highest per cent incidence was of *Fusarium moniliforme* (Table-1). *A.flavus* had only 15 per cent incidence. During summer (April - May) *A. flavus* was dominant whereas the presence of *F. moniliforme* was low. During monsoon, when the humidity increased, incidence of *A. flavus* increased to 85 per cent. In contrast, the occurrence of *Fusarium* sp. was low.

The dominance of *A.flavus* in kothi was lesser than in gunny bag (Table-2). However the difference was not remarkable during the winter and summer seasons but significant in monsoon.

Out of 140 isolates, 36 were positive to toxin production and 12 produced aflatoxin B<sub>1</sub>. Isolates producing both B<sub>1</sub>, B<sub>2</sub> were 14. Five isolates produced G<sub>1</sub> along with B<sub>1</sub>& B<sub>2</sub>. Only 5 isolates produced the aflatoxins - B<sub>1</sub>,B<sub>2</sub>, G<sub>1</sub> &

W re extracted chemically for aflatoxins  $G_2$ . The 12 isolates produced variable amounts (T tomas *et al.*, 1975).  $G_2$ . The 12 isolates produced variable amounts of the toxin (Table-3), which ranged from 10 to 2230 ppb.

#### AFLATOXIN IN BRASSICA

The seeds were tested for the aflatoxin. Out of 32 mustard seed samples, 20 gave BGY fluorescence (Table-4). Further screening revealed that 12 had natural occurrence of aflatoxin which ranged from "trace" to 750 ppb.

**DISCUSSION** - The variation in per cent incidence of A. flavus on mustard sceds is due to fluctuation in atmospheric humidity. This is clearly evident by the increase in A. flavus during monsoon. Surprisingly, during summer also high population was recorded. The internal moisture released on account of respiration by the seeds may have favoured the fungal growth.

Dominance of A. flavus in gunny bag in the monsoon is apparently due to easy access of atmospheric moisture to the seeds. But, this is FENNELL DI, RJ BOTHAST, E BLILLEHOJ & R E PETERSON 1973 Bright Greenish-yellow flourescence and associated fungi in corn naturally contaminated with aflatoxin Cereal Chem 50 404 - 414.

restricted by the thick wall of kothi which is also made air tight to some extent by closing the exit and entry points.

Potential importance of mycotoxins in the health of man and his domestic animals has been well realized by the investigations in the recent past (Wyllie & Morehouse, 1977).

All the isolates of A. flavus were not toxigenic. Only 5 isolates produced aflatoxin B<sub>1</sub>, B<sub>2</sub>, G<sub>1</sub> & G<sub>2</sub>. Toxigenic and non-toxigenic strains could not be distinguished morphologically.

Because mustard is used throughout the country, there is likelihood of the danger of aflatoxicosis to the consumer. This is more so because it is thermostable (Kush & Gupta, 1982).
